# Safe Receding Horizon Motion Planning with Infinitesimal Update Interval

Inkyu Jang, Sunwoo Hwang, Jeonghyun Byun, and H. Jin Kim Department of Aerospace Engineering, Seoul National University, Seoul, Korea.

### Summary

- We take <u>infinitesimal update interval</u> for a safety-aware receding horizon motion planning problem to get a <u>real-time safety filter</u>.
- The proposed algorithm is <u>safe</u>, <u>recursively feasible</u>, and runs in <u>real-time</u>.
- The proposed motion planning method was validated through <a href="https://example.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardware.com/hardwar

# Notes on the Replanning Interval

- It denotes <u>how promptly the system can respond</u> to possibly changing environmental conditions.
- → It is favorable to keep the interval as short as possible.
- It serves as the <u>time budget to complete searching</u> for the next trajectory.
- → It <u>cannot be shortened</u> beyond the robot's onboard computation capacity.

# In this work, we consider the limit replanning interval $\searrow$ 0.

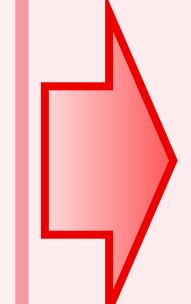

#### Trajectory parameter optimization

min. 
$$J(k)$$
 (trajectory cost)

s.t.  $x(k,0) = x$  (initial condition)

 $w(k) \ge 0$  (safety)

 $\rho(k) \ge 0$  (parameter feasibility)

- Trajectory parameter <u>change rate</u> optimization
  - $\begin{array}{ll} \underset{u,\dot{k},\dot{\tau}}{\min} & \partial_k J(k) \cdot \dot{k} + \lambda \dot{\tau} + \frac{1}{2} \mu_k \|\dot{k}\|^2 + \frac{1}{2} \mu_\tau \dot{\tau}^2 & \text{(trajectory cost change rate)} \\ \text{s.t.} & \partial_k x(k,\tau) \cdot \dot{k} + \partial_\tau x(k,\tau) = f(x) + g(x)u & \text{(initial condition)} \\ & \partial_k w(k) \cdot \dot{k} + \alpha \big( w(k) \big) \geq 0 & \text{(safety)} \\ & \partial_k \rho(k) \cdot \dot{k} + \gamma \big( \rho(k) \big) \geq 0 & \text{(parameter feasibility)} \\ & \dot{\tau} + \sigma(\tau) \geq 0 & \text{(trajectory starting point feasibility)} \\ & u \in U & \text{(input feasibility)} \end{array}$
- Feasibility not guaranteed, <u>needs an</u>
   <u>emergency brake maneuver</u> for safety.
- Nonlinear, nonconvex optimization, heavy computation.
- The update interval cannot be shortened beyond the robot's onboard computation power.
- The trajectory cost is replaced with its time derivative, plus some auxiliary terms for numerical stability.
- Equality constraint satisfied indirectly using time derivatives.
- Inequality constraint satisfied using CBF-QP-style class-K functions.
- ✓ Convex quadratic program (QP), which can be solved in real-time.
- $\checkmark$  Safety filter that directly gives the input u.
- ✓ Recursively feasible, given the trajectories satisfy final stop conditions.

x, u: State and input variables

k : Trajectory parameter

- au: Indicator at which time point on the parametrized trajectory the robot will start
- J(k): Differentiable trajectory cost
- $\mathbf{x}(k,\tau)$ : Parametrized trajectory with final stop condition
- v, 
  ho : Differentiable safety and feasibility constraints
- $\alpha, \gamma, \sigma$ : Element-wise class-K functions

# Experiment Result

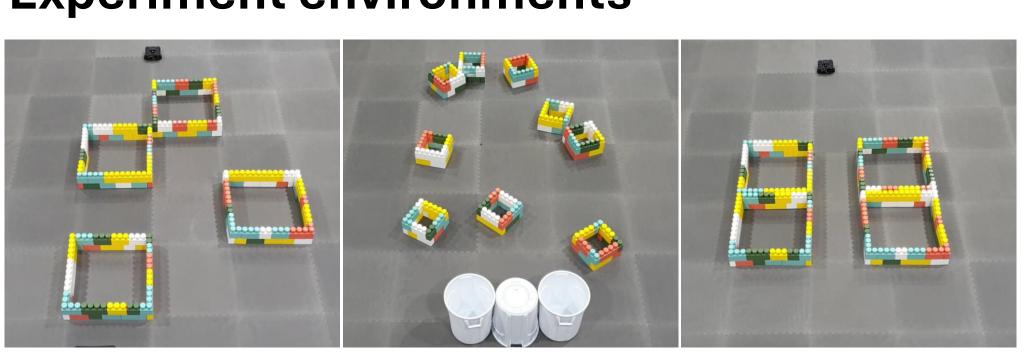

#### **Experiment setting**

- Diff-drive robot, controlled by linear / angular accelerations.
- 2D LiDAR sensor which scans obstacle distance from all directions. (up to 360 points)

#### Safety requirements

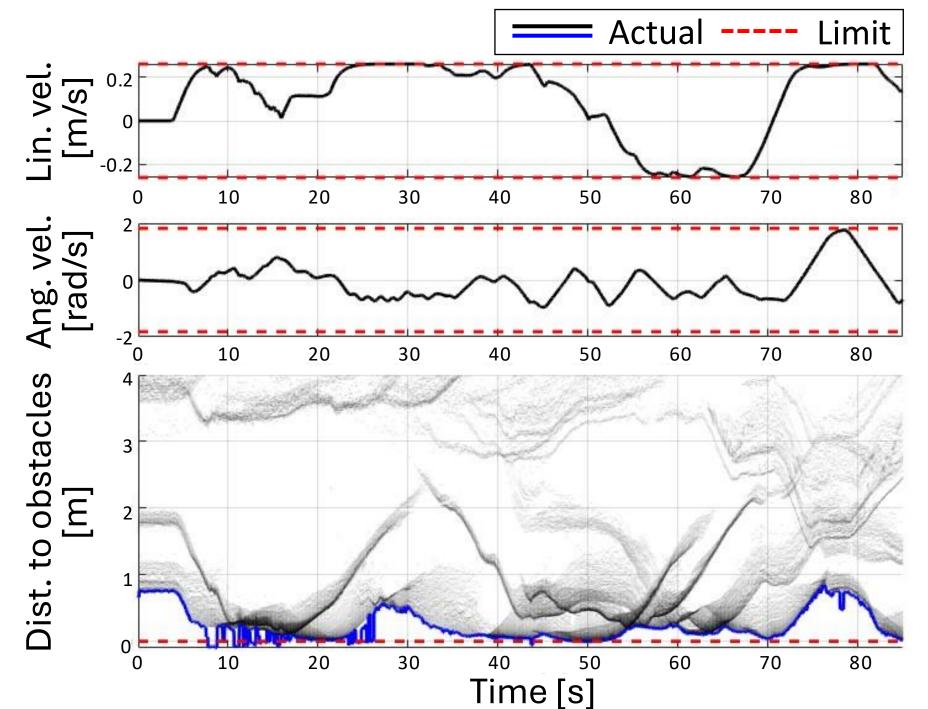

- Collision avoidance with all the LiDAR points.
- Linear / angular speed limits

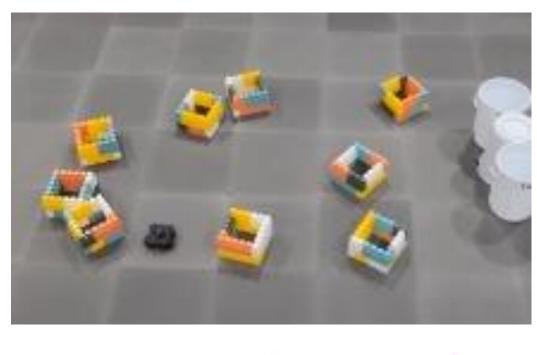

#### **Experiment environments**

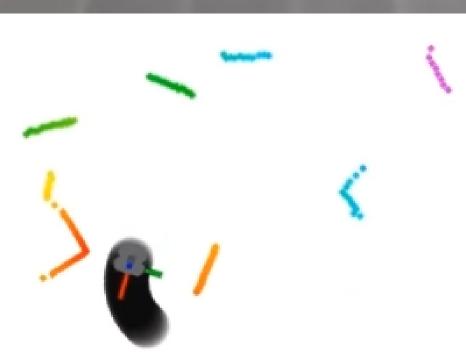

- The <u>trajectory cost was given in an aggressive way</u> that the robot is driven towards the obstacles.
- Even under aggressive trajectory cost, the robot was able to <u>avoid hundreds of LiDAR points simultaneously</u> using onboard computation only.

A snapshot from the experiment.
